

User Defaults

- UserDefaults are meant to be used to store small pieces of data which persist across app launches.
- It is very common to use UserDefaults to store app settings or user preferences.
- UserDefaults lets you store key-value pairs, where a key is always a String and value can be one of the following data types:String, Number, Date, Array or Dictionary.

- UserDefaults saves its data in a local plists file on disk.
- UserDefaults are persisted for backups and restores.
- For example, you can allow users to specify their preferred units of measurement or media playback speed. Apps store these preferences by assigning values to a set of parameters in a user's defaults database.

- The parameters are referred to as defaults because they're commonly used to determine an app's default state at startup or the way it acts by default.
- At runtime, you use UserDefaults objects to read the defaults that your app uses from a user's defaults database.
- UserDefaults caches the information to avoid having to open the user's defaults database each time you need a default value.
